

Java script events

Java script interaction with HTML is handled through events that occurs when the user or browser manipulate a page. when the page loads , it is called an event. When the user clicks a button , that click is an event. Another examples are pressing any key, closing a window, resizing a window etc. Events are the actions that can be detected by javascript. Most commonly used events are

- 1.onload : browser has finished loading the page
- 2.keypress : when user press any key
- 3.onclick : user click on any html elements
- 4.onchange : html element has been changed
